

Supporting Information

The European Union Policy-Making Dataset

Frank M. Häge

Department of Politics and Public Administration

University of Limerick

SUMMARY

The supporting information in this online appendix consists of a more detailed description of the information extraction procedure and additional tables and figures that are not essential to but support the analysis reported in ‘The European Union Policy-Making Dataset’. The tables are also available in MS Excel format at www.frankhaege.eu.

Additional tables and figures

Table SI-1 Number of documents by type of file

<i>Type of file</i>	<i>Freq.</i>	<i>Percent</i>	<i>Cum.</i>
Regulation	8,994	31.18	31.18
Decision	5,850	20.28	51.46
Communication	4,082	14.15	65.61
Report	3,441	11.93	77.54
Directive	1,990	6.90	84.44
Transfer of appropriations	1,498	5.19	89.63
Working paper	1,363	4.73	94.36
Opinion	349	1.21	95.57
Assent	294	1.02	96.59
Recommendation	242	0.84	97.42
Preliminary draft supplementary budget	105	0.36	97.79
Resolution	101	0.35	98.14
Green paper	94	0.33	98.46
Letter of amendment	83	0.29	98.75
Preliminary draft budget	65	0.23	98.98
Framework decision	44	0.15	99.13
Memorandum	40	0.14	99.27
White paper	29	0.10	99.37
Periodic report	25	0.09	99.46
Programme	25	0.09	99.54
Letter	23	0.08	99.62
Act	17	0.06	99.68
Protocol	16	0.06	99.74
Common position	12	0.04	99.78
Declaration	11	0.04	99.82
Member states agreement	9	0.03	99.85
Agreement	8	0.03	99.88
Declaration	8	0.03	99.90
Note	7	0.02	99.93
ECSC budget	6	0.02	99.95
Interinstitutional agreement	6	0.02	99.97
MISSING	4	0.01	99.98
Joint action	3	0.01	99.99
Treaty	2	0.01	100.00
Total	28,846	100.00	

Table SI-2.1 Number of proposals by type of legislative procedure

<i>Type of procedure</i>	<i>Freq.</i>	<i>Percent</i>	<i>Cum.</i>
Consultation	6,166	66.28	66.28
Agreement	1,170	12.58	78.86
Codecision	1,112	11.95	90.81
Cooperation	580	6.23	97.04
Assent	251	2.70	99.74
Consultation ECB	16	0.17	99.91
Consultation CoA	3	0.03	99.95
Social Protocol	3	0.03	99.98
Special Legislative	2	0.02	100.00
Total	9,303	100.00	

Table SI-2.2 Number of proposals by type of legislative procedure
(including no procedure)

<i>Type of procedure</i>	<i>Freq.</i>	<i>Percent</i>	<i>Cum.</i>
No procedure	19,543	67.75	67.75
Consultation	6,166	21.38	89.13
Agreement	1,170	4.06	93.18
Codecision	1,112	3.85	97.04
Cooperation	580	2.01	99.05
Assent	251	0.87	99.92

The information extraction procedure

The extraction procedure consists of three computer scripts written in the programming language Python. The three scripts are run sequentially. The first script downloads the proposal pages of the PreLex database and saves their HTML source code in text files, the second script extracts and stores the information contained in those pages in a Python dictionary, and the third script writes the extracted information from the dictionary to a comma-separated file. In the latter format, the data can then be imported into a statistical software package for further processing. In the following, I describe each of these steps in more detail.

Download

The download script first opens the standard search page of the PreLex database, enters a year into the corresponding search field (see Figure SI-8), and then executes the search. The search retrieves references to all documents submitted by the Commission to the other institutions during the specified year. The search results are returned in the form of a number of search result pages, each containing a list of up to 20 links to other pages that contain the actual proposal descriptions (see Figure SI-9). The script identifies all the links on the first search results page. These links are used to download the proposal pages and to save their HTML source code in text files on the local hard drive. The web address of each proposal page contains a unique identification number (see Figure SI-10). This number is used as a name for the text file in which the HTML code is saved. Later, this number is also used in the dataset as a case identifier. Furthermore, the information extraction algorithm outlined below relies on a list of these page numbers to loop through all the HTML text files.

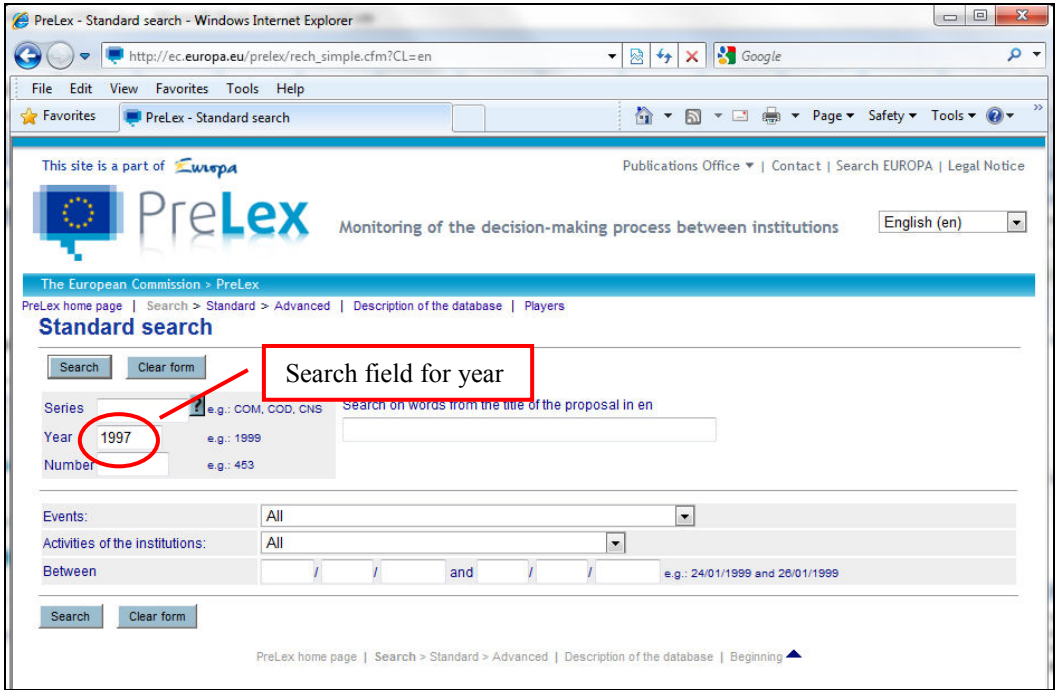

Figure SI-8 Standard search page of PreLex database

Note: PreLex' standard search page can be accessed at http://ec.europa.eu/prelex/rech_simple.cfm?CL=en (2 July 2010)

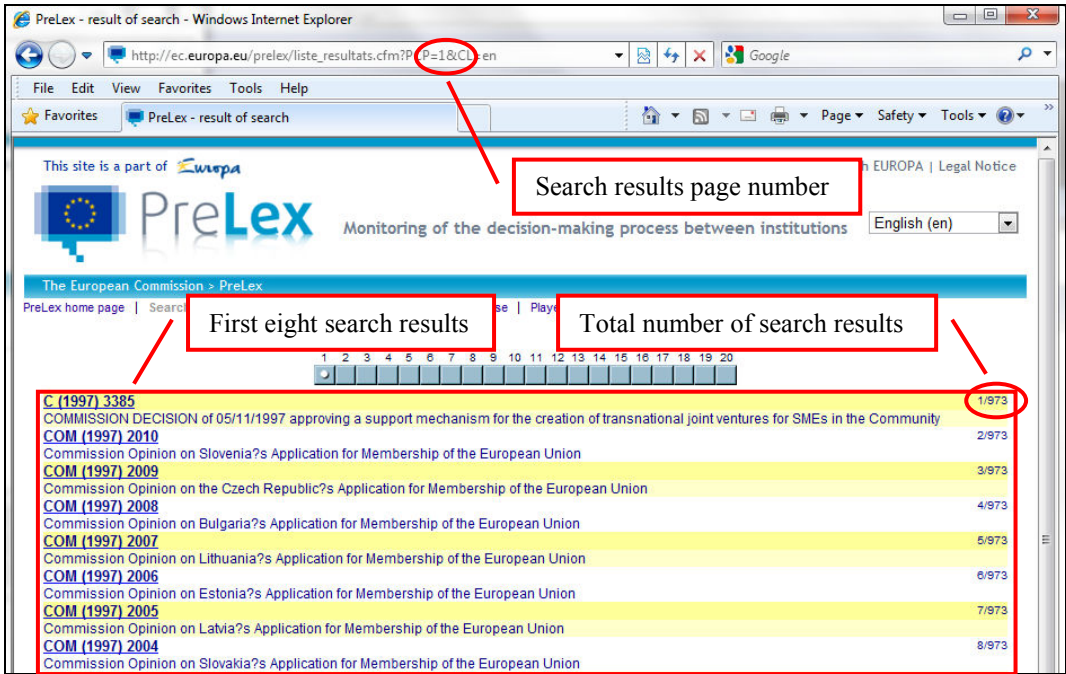

Figure SI-9 Example of first search results page of PreLex database

Note: This page does not have a permanent web address but can be accessed by searching for the year '1997' on the standard search page, which is itself accessible at http://ec.europa.eu/prelex/rech_simple.cfm?CL=en (2 July 2010).

After having downloaded all proposal pages referenced on the first search results page, the script continues the download on the next search results page until no further search results exist. All search results pages indicate the total number of documents found (see Figure SI-9). The web addresses of the search results pages differ only in their page number, which indicates the running number of the first search result presented on that page. Each search results page presents 20 results. Thus, in order to move to the next search results page, 20 is added to the number at the end of the current web address. The resulting new web address is used to open the next search results page. This procedure is repeated as long as the resulting number is smaller than the total number of search results indicated on the search results page (see Figure SI-9). On each search results page, the script identifies all links to proposal pages and saves their HTML source code one after the other under their respective page number. As an example of one of these pages, Figure SI-10 shows the upper part of a page that documents the adoption of a proposal for a Council Directive introduced in 1997¹. After the script has looped through all search results pages of a certain year, it returns to the standard search page of the database and enters another year into the search field. In this way, the script loops through all years from 1958 to 2010 and downloads all proposal pages. The PreLex database is continuously updated by Commission officials. Thus, saving and preserving the pages in their current form ensures that the information extraction process can be replicated in the future even if the online files have been modified in the meantime.

¹ The example page can be accessed at http://ec.europa.eu/prelex/detail_dossier_real.cfm?CL=en&DosId=108000 (2 July 2010)

Information extraction

The list of proposal page numbers generated during the download and the text files with the HTML source code constitute the input files for the information extraction procedure. For each page number, the script first generates the name of the text file holding the HTML code of the page. It uses this file name to open and load the HTML code into memory. The extraction begins by identifying the part of the HTML table that contains the title of the Commission document, the Commission document number, and, if applicable, the legislative procedure number (see Figure SI-10). These three pieces of information are always contained in the same cells of the HTML table, which implies that they can be located by navigating through the structure of the HTML code; no knowledge about the content of the page is required to identify their location. The content of each cell is then stripped of any HTML code and saved as a variable value in a Python dictionary².

² These three are the only variables for which the variable name is not generated by the script but actually defined at the start of the extraction process.

Figure SI-10 Example page from PreLex database

Note: The page can be accessed online at http://ec.europa.eu/prelex/detail_dossier_real.cfm?CL=en&DosId=108000 (2 July 2010)

Unfortunately, the information in the remaining parts of the proposal page is not always located in the same HTML table cells. However, it is always located in the same cells relative to each other. The remaining parts of the page are divided into what could be called the header and the body (see Figure SI-10). If one of the cells within these parts of the page has been located correctly, all other content can be identified by navigating

through the HTML structure. The header contains information about some general characteristics of the dossier (i.e. the fields of activity, the legal basis, the type of file, and the legislative procedure). But to locate the first relevant cell, some knowledge about the content of the page is required. To identify the header part of the page, the script searches for the cell that includes the text 'Fields of activity'. The 'Fields of activity' cell is included on all of the pages, even in cases where no information about the fields of activity is actually provided. Therefore, this reliance on the content of the page does not impair the robustness of the script. From the 'Fields of activity' cell, the entire HTML table containing the remaining information of the header can be identified. Now, the script loops through each of the rows of the header table. It extracts the content of the left cell to create the variable name and the content of the right cell to create the variable value.

Once all the information from the header is extracted, the procedure moves on to the body of the page (see Figure SI-10). Again, one of the cells of the body table of the page has to be identified to browse through and correctly extract the information from the remaining cells. This time, the identification of the cell is done by searching for 'Adoption by Commission'. Since most dossiers included in PreLex are documents generated by the Commission, almost all pages contain this cell. The only exception occurs when a legislative proposal is based on a member state initiative. Such member state initiatives are possible in the area of Justice and Home Affairs since the Maastricht Treaty came into force in 1993. The starting event in these cases is the 'Transmission to Council'. Thus, in cases where the search for 'Adoption by Commission' yields a negative result, the script searches for 'Transmission to Council' and takes this cell as the starting point for the further extraction of the information in the remainder of the

body table. Once that cell has been identified, the script loops through all rows of the body table. If a row provides information about an event, then the right cell describes the event, and the left cell gives the date of the event. Exploiting this structure, the information in the right cell is used to generate the variable name and the information in the left cell is used to generate the variable value, which in this case is a date. If a row provides information about an event characteristic, the left cell describes the event characteristic and the right cell describes its value. In this case, the left cell is used to generate the variable name and the information in the right cell is extracted as the variable value. The script checks whether a row includes information about an event or about an event characteristic by examining whether the left cell of the row contains a date. For example, the content of the first row of the body table of the page shown in Figure SI-10 would be recognized as an event because the cell to the left of the cell containing the text 'Adoption by Commission' contains a date.

In general, when the information describing an event or an event characteristic is extracted to generate a variable name, the HTML code surrounding the text in the respective cell is first removed. Then the text is converted to lower case letters. If the text consists of more than one word, the words are abbreviated to four letters and merged into a single word, with each of the words' initial letters being capitalized to aid readability. In addition, the term 'date' and a running number are added to the variable name. For example, the event 'Adoption by Commission' results in the abbreviated variable name 'adopByComm_date_0'. In the case of an event characteristic, the abbreviated variable name also receives a running number and is then added to the abbreviated variable name of the event and the event's running number. Thus, the event characteristic 'Mandatory consultation' in Figure SI-10 is abbreviated to 'mandCons'

and concatenated with the event abbreviation ‘adopByComm’ and their respective running numbers, which leads to the variable name ‘adopByComm_0_mandCons_0’. Since the same event characteristic can refer to different types of events, this concatenation of event and event characteristic in the name of the variable ensures that the event characteristic is unambiguously related to the corresponding event.

As the inclusion of running numbers in the variable name indicates, both events and event characteristics can occur several times within the same proposal page. In the example page (see Figure SI-10), both the Economic and Social Committee and the European Parliament is listed as institutions for which consultation is mandatory. Thus, the event characteristic ‘Mandatory consultation’ has two different values. In such cases, the script splits the content of the cell containing the event characteristic descriptors, creates separate variables for each descriptor, and adds a running number to their names to distinguish between them. In the example, the need for mandatory consultation of both institutions results in the generation of two variables, ‘adopByTheComm_0_mandCons_0’ and ‘adopByTheComm_0_mandCons_1’; the first variable has the value ‘Economic and Social Committee’ and the second variable has the value ‘European Parliament’. Some type of events can also occur several times. The script keeps track on how often an event occurred in the context of the current page. When generating a new variable name for an event, it updates and assigns the appropriate running number. The large number of variables in the dataset is largely due to events occurring repeatedly in a single decision-making process and due to event characteristics having several descriptors.

Data storage

The newly generated variable names and the variable values are initially saved in a Python dictionary. Data in these dictionaries have two related components. One component is the so-called key and the other component is the key's value. In this application, the variable names are stored as keys and the substantive event descriptions are stored as values. A hierarchical data structure can be developed simply by nesting one dictionary in another. Thus, for each individual page, a dictionary is created containing the extracted variable names and associated variable values. The proposal page dictionaries in turn form the values of a larger dictionary that lists these dictionaries by their page number as key. While this construction seems awkward, it has the major advantage of allowing the dataset to be built from the bottom up. Prior to the start of the information extraction process, no knowledge about the number of observations or the number of variables is required.

Once the extraction script has looped through the list of proposal page numbers, all information is stored in the Python dictionary. While the dictionary is a convenient object to temporarily save the information gathered during the extraction process, the information still has to be written to a file type that can be imported into statistical software packages. The most basic and common file type for this purpose is a comma-separated text file. However, the information in the original dictionary has to be brought into a more standardized table format before it can be written to such a file. The original dictionary is organized by page numbers as keys, with the associated values being smaller dictionaries themselves, linking events and event characteristics of the proposal page with their respective values. To develop a more table-like data structure, the storage script generates a simpler dictionary that takes events and event characteristics

(i.e. the variable names) as keys and the associated descriptors as values. The script first extracts all variable names from the original dataset, eliminates duplicates, and generates a new, empty dictionary with those variable names as keys. Then it loops through the original dictionary and stores the variable value or, if the event or event characteristic was not present in the case, a missing value in the list of values related to those variable names. Once all information is included in the new table-like dictionary, the script iterates over the variable names of this dictionary to extract the values from an individual page and write them to the text-file. In this manner, the values for individual proposal pages are added to the text file line by line.

List of variables

Note that this list includes only those 680 variables that describe the first occurrence of a certain event and the first characteristics of a certain event descriptor. The names of the remaining variables in the dataset are derived in a similar manner. They only differ in that the running numbers for the event and the event descriptor are not zero.
